ABSTRACT

Background: The case control study, an analytical approach of epidemiology is a very important tool to detect the strength of association of risk factors with a disease. The objective of the study was to evaluate association between sociodemographic profile and pulmonary tuberculosis.

Methods: This was case control study carried out in tertiary care hospital and urban field practice area from July 2010 to November 2012. Total 150 cases, 150 hospital control and 150 community controls were included in the study according to predefined inclusion and exclusion criteria. The study participants were interviewed and examined according to the preformed and pretested proforma in the respective OPDs.

Results: Mean age of cases was found to be 35.94 years and those of hospital controls and community controls were 36.12 and 36.08 years respectively. Maximum cases and controls were Hindu, married, from urban area and belongs to upper lower socioeconomic class. Low socioeconomic status was found to be associated with risk of pulmonary tuberculosis and this association was statistically significant (OR=4.45, 95% CI 2.53–7.82, p<0.0001).

Conclusions: Low socioeconomic status showed significant association with pulmonary TB with both the control groups.

Keywords: Socioeconomic status, Tuberculosis, Case-control

INTRODUCTION

Today’s is the era where best diagnostic techniques and almost 100% curative treatment regimens for tuberculosis are available. But, still this disease contributes a major part to the morbidity and mortality figures affecting almost all age groups.

All this has made the researchers in health field rethink upon whether it is just the bacterium which is responsible for the disease or there are the factors which make a person susceptible for occurrence of the disease. This thought is strengthened by the fact that two out of every 5 Indians are infected with TB Bacillus. But, it is not that all of them develop the disease. Once infected, there is 10% life time risk of developing the disease.¹

The case control study, an analytical approach of epidemiology is a very important tool to detect the strength of association of risk factors with a disease. Present study was carried out to evaluate association between sociodemographic profile and pulmonary tuberculosis. Results were drawn with two sets of controls separately i.e. hospital controls and community controls to find out an appropriate control group in case control studies.

Objective

To evaluate association between sociodemographic profile and pulmonary tuberculosis.
METHODS

Study design

Case-control study

Study participants

Cases: New cases of smear positive pulmonary tuberculosis attending TB and Chest OPD.

Hospital controls: Patients attending medicine OPD.

Community controls: Residents of Urban Health Field Practice Area.

Duration of study period

July 2010 to November 2012

Study setting

For cases: TB and chest OPD of the Medical College and Hospital.

For hospital controls: Medicine OPD of the Medical College and Hospital.

For community controls: Urban health field practice area of the Medical College.

Selection of cases and controls

Case definition: A ≥15 years old patient with c/o cough for more than 2 weeks and found to be positive for tubercle bacilli on sputum smear examination.

Control definition: A person matched for age (±5 years) and sex who were not having c/o cough for more than 2 weeks and were ≥15 years old. Two controls were taken against every case, one hospital control from Medicine OPD and the other community control from the urban health field practice area. One to one age and sex matching was done.

Inclusion criteria

The participants who fulfilled the criteria mentioned in case and control definitions.

Exclusion criteria

Persons having H/O tuberculosis were excluded from the study.

Sample size estimation

On the basis of findings of pilot study, proportion of exposure (history of contact with case of tuberculosis) in cases was found to be 18% and in hospital controls it was 8%.

\[ p_1 = \text{Proportion of exposure in the diseased population} = 0.18. \]

\[ p_2 = \text{Proportion of exposure in the control population} = 0.06. \]

\[ q_1 = 1 - p_1, \]

\[ q_2 = 1 - p_2. \]

\[ \alpha = \text{level of significance} = 0.05 \]

\[ \beta = \text{claiming that exposure is not associated with disease when in fact it is} = 0.01 \]

\[ Z_\alpha = 1.96, Z_\beta = 1.28 \]

Sample size was determined by the following formula:

\[ N = \frac{(Z_\alpha + Z_\beta)^2 (p_1 q_1 + p_2 q_2)}{(p_2 - p_1)^2} \]

\[ N = 137. \]

Approval from institutional ethics committee and Maharashtra University of Health Sciences (MUHS), Nashik was taken before commencing the study. After informed and written consent was sought, the study participants were interviewed and examined according to the preformed and pretested proforma in the respective OPDs.

The TB and chest OPD was visited daily for cases. Visit was given to the Medicine OPD for matched controls. The community controls were taken within 7 days of the interview of the cases. The proforma included detailed information about demographic characteristics (such as age, gender, marital status, education, occupation and socioeconomic status).

Statistical analysis

Statistical analysis was done by percentages, odds ratio, 95% confidence intervals, and chi square test as a test of significance. \( P < 0.05 \) was taken as statistically significant. Software Episinfo version 7.1 was used for statistical analysis.

RESULTS

Table 1 shows that there were total 107 (71.33%) males and 43 (28.67%) females in each group giving a male to female ratio of 2.5:1. Most of the cases i.e. 133 (88.67%) belonged to age group of 15 to 55 years. Mean age of cases was found to be 35.94 years and those of hospital controls and community controls were 36.12 and 36.08 years respectively.

Table 2 shows that 140 (93.33%) cases and 137 (91.33%) hospital controls belonged to urban area. Only 10 (6.67%) cases and 13 (8.67%) hospital controls were
from rural region. All the community controls belonged to the urban area.

Among cases, total 120 (80%) cases belonged to upper lower class, of the 150 hospital controls 97 (64.67%) study participants belonged to upper lower class and of the 150 community controls, total 87 (58%) study participants belonged to upper lower class.

Table 4 shows that of 150 cases, hospital controls and community controls maximum belonged to Hindu religion i.e. 88 (58.67%), 81 (54%) and 111 (74%) respectively.

Table 5 shows that of 150 cases, hospital controls and community controls maximum belonged to married group i.e. 92 (61.33%), 92 (61.33%) and 101 (67.33%) respectively.

There were 129 (86%) cases, 105 (70%) hospital controls and 87 (58%) community controls in the category IV and V SES. Low socioeconomic status (class IV and V) was found to be associated with risk of pulmonary tuberculosis and this association was statistically significant (OR=2.63, 95% CI 1.48 - 4.70, p=0.0008).

On analysis of cases versus community controls, low socioeconomic status was found to be associated with risk of pulmonary tuberculosis and this association was statistically significant (OR=4.45, 95% CI 2.53–7.82, p<0.0001).

**DISCUSSION**

**Age and sex of the study participants**

In the present study, age (±5 years) and sex matching was done. Study participants were aged ≥15 years. Male to female ratio was found to be 2.5:1. Maximum age of the study participant was 75 years. In a study conducted by Hill et al on study participants ≥15 years, male to female ratio was found to be 1.86:1. Gupta et al found male to female ratio of 3.7:1. Shetty et al conducted a study on participants in the range of 15 to 83 years and the sex distribution was 58% men and 42% women. It is evident from the above findings that prevalence of the disease is more in males as compared to females. In most of the studies, minimum age limit considered was 15 years because some risk factors like smoking, alcohol intake and chronic diseases like diabetes mellitus arise after this age only. Same holds true for the present study.

**Place of residence**

In the present study, 140 (93.33%) cases and 137 (91.33%) hospital controls and 150 (100%) community controls belonged to urban area. Only 10 (6.67%) cases and 13 (8.67%) hospital controls were from rural area. In a study conducted by Behera et al, there were 44 (46.3%) cases and 46 (42.2%) controls from rural area and 51 (53.7%) cases and 63 (57.8%) controls from urban area. Kaulagekar et al conducted a study using data obtained from NFHS–2 and found that prevalence of TB in urban males and females was 0.50% and 0.41% respectively and it was 0.73% and 0.54% in rural males and females respectively. There were 50 (81.90%) cases and 104 (85.20%) controls from urban region and 11 (18.10%) cases and 18 (14.80%) controls from rural area in a study conducted by Alavi et al.

**Religion**

In this study, maximum cases, hospital controls and community controls belonged to Hindu religion i.e. 88 (58.67%), 81 (54%) and 111 (74%) respectively. In a study conducted by Shetty et al, there were 136 (72%) study participants of Hindu religion among cases and 128 (67.70%) in controls. In this study, maximum cases, hospital controls and community controls were married and 71 (37.6%) cases and 72 (38.1%) controls were unmarried, widowed or separated. Present also yielded similar findings.

**Marital status**

In this study, most of the study participants among cases, hospital controls as well as community controls were married i.e. 92 (61.33%), 92 (61.33%) and 101 (67.33%) respectively. In a study conducted by Hill et al, 48 (48%) cases and 118 (59%) controls were married, 43 (43%) cases and 74 (37%) controls were single and 9 (9%) cases and 8 (4%) controls were widowed/divorced. In a study by Behera et al, 98 (89.9%) controls and 80 (84.2%) cases were married. Shetty et al conducted a case control study. In their study, 118 (62.4%) cases and 117 (61.9%) controls were married and 71 (37.6%) cases and 72 (38.1%) controls were unmarried, widowed or separated.

**Socioeconomic status**

In the present study, on multivariable analysis, SES showed significant association with pulmonary TB only on analysis with hospital controls. For analysis purpose,
the study participants were clubbed into 2 groups. Study participants in the category IV and V of socioeconomic class were kept in one group and those in the category I, II and III in in another. 129 (86%) cases were in the category IV and V SES against the 105 (70%) hospital controls and this difference was found to be statistically highly significant with risk of pulmonary tuberculosis more with low socioeconomic status (OR=2.63, 95% CI 1.48-4.70, p=0.0008). 87 (58%) community controls were found to be in category IV and V socioeconomic status. The difference between cases and community controls was also found to be statistically significant with risk of pulmonary tuberculosis more with low socioeconomic status (OR=4.45, 95% CI 2.53–7.82, p<0.0001). But, on multivariable analysis, it remained significant only on comparison with hospital controls after adjustment for hypertension, smoking, alcohol intake, H/O TB contact, BCG scar (adjusted OR=2.47, 95% CI 1.31–4.66, p=0.005).

Clark et al, in their study concluded that rise in community household income appeared to decrease risk by four times (parameter estimate= -1.4285, OR=0.24, 95% CI 0.10–0.56, p=0.0010).10 Gupta et al found that odds ratio (OR) increased by 3.14 (95% CI 2.48-3.98) for every decrease of Rs. 500/- in the income level per person per month below Rs. 2000/-, showing the association to be statistically significant (p<0.001).11 Shetty et al found that socioeconomic status was found to be a non-significant risk factor after adjustment for other factors (adjusted OR=0.52, 95% CI 0.25-1.10, p=0.08).9

CONCLUSION

Most of study participants were Hindu, married and resided in urban area. Low socioeconomic status showed significant association with pulmonary TB with both the control groups.
