ABSTRACT

Background: Acute respiratory infection (ARI) is an infection of the respiratory tract that may interfere with normal breathing. ARI is one of the leading causes of illness and death among children worldwide. The aim of the study was to estimate the prevalence of ARI among under 5 children in the rural field practice area of a medical college in Kancheepuram district of Tamil Nadu.

Methods: This study is a community based cross-sectional study. The study population was children below five years of age and informant was the mother of the child. The sample size is 380 and simple random sampling method was used. Data was analyzed using the SPSS software, version 16, and presented as descriptive statistics.

Results: The prevalence of ARI among children was 41.6%. Regarding the symptoms of ARI, 36.6% of them had either cold or runny nose, 27.9% had cough, 23.4% had stridor, 20.8% had reduced intake of food, 2.6% had either ear pain or discharge, 2.6% had rapid breathing, 1.3% had wheeze, 0.8% were tired/drowsy, 0.5% had throat pain, 0.5% had convulsions and 17.1% of them had symptoms with fever.

Conclusions: This study shows the prevalence of ARI among children below 5 years of age is 41.6% which is relatively high. The symptoms of ARI reflect the non severe form of pneumonia. More hospital based studies should be done in order to know the burden of severe form of pneumonia which contributes to the morbidity and mortality of children below five years of age.

Keywords: Respiratory tract, Infectious diseases, Pneumonia, ARI

INTRODUCTION

Acute respiratory infection (ARI) is an infection of the respiratory tract that may interfere with normal breathing. They are infectious in nature and can spread from person to person.1 ARIs are the most common cause of illness and death in children belonging to the age group of 1 to 60 months (under 5 except neonatal period). The severity of the disease varies between developed and developing countries and due to differences in aetiology and risk factors. ARI such as pneumonia is one of the most fatal communicable diseases among the children worldwide.2 The burden of ARIs falls heavily on developing countries.

ARI can be classified as upper respiratory tract infections and lower respiratory tract infections. Anatomically, the upper respiratory tract extends from the nostrils to the vocal chords in larynx including the paranasal sinuses and middle ear. The lower respiratory tract covers the continuation of airways from trachea to bronchi to bronchioles and alveoli. The upper respiratory tract infections are more common and more commonly attributed to viral aetiology, namely, rhinovirus, respiratory syncytial virus (RSV), parainfluenza/influenza virus, adenovirus, etc.

Most of the upper respiratory tract infections are self limiting. Acute viral infections can predispose children to...
bacterial infections of sinuses and middle ear and can result in lower respiratory tract infection by aspiration of infected secretions and cells. ARIs are not confined to the respiratory tract alone and can be systemic also. The severity due to lower respiratory tract infections is worse in developing countries. This also results in higher case fatality rates. Majority of ARI deaths and severe illness episodes are due to acute lower respiratory tract infections especially due to pneumonia.

The common signs and symptoms of ARI are blocked nose or runny nose, cough, ear ache or ear discharge, sore throat, noisy breathing such as wheeze or stridor and difficult breathing like chest in-drawing and fast breathing.

Acute respiratory infection is one of the leading cause of illness and death among children worldwide. The state of child health as such is that, 5.9 million children below 5 years of age died in 2015, accounting to nearly 16,000 every day. Almost 83% of deaths are due to infectious diseases, neonatal or nutritional conditions. Among the neonatal deaths, death due to pneumonia was 2% and among the post neo natal death, deaths due to pneumonia was around 13%. Around 20 to 40% of all child hospitalisations were due to ARI and pneumonia alone accounts to 20% of all paediatric deaths which was around 1.6 million in 2008.

The serial National Family Health Survey studies reported an overall prevalence of ARI as 6.5% (NFHS 1, 1992-93), 19% (NFHS 2, 1998 - 99) and 5.8% (NFHS 3, 2005 - 06) among under 5 children. In Tamil Nadu, as per NFHS 4 (2015 - 2016) the prevalence of symptoms of ARI among under five children is 2.8% (rural- 2.7%, urban- 2.9%). The same survey reported that in Kancheepuram, the prevalence of symptoms of ARI is 2%

Every day in the outpatient department of the Rural Health Training Centre (RHTC) attached to a medical college in Kancheepuram district, children with different clinical presentation of ARIs are reporting for management. On an average the centre treats about 5 to 7 under five children with ARI per day. In order to know the prevalence and further our knowledge to understand the epidemiology of ARI, this study was conducted to estimate the prevalence of ARI among the under 5 children in the field practice area of a medical college in Kancheepuram district.

METHODS

Study design

This study is a community based cross-sectional study.

Study area and study population

The study was done in Sripuram, rural field practising area of Sree Balaji Medical College and Hospital in Kancheepuram district of Tamil Nadu. The total population of the study area was 36,830. Among this, the total number of children below five years of age is 3494. The study was done among children belonging to the age group of 1-60 months (under five) in the study area. In this study the informant was the mother of the child. The study was carried out from August 2016 to August 2017.

Sample size

According to a previous study done by Kumar et al during 2014 in a rural area of Puducherry, the prevalence of ARI among children below 5 years was 53.7%. This was taken as a reference value for sample size calculation. The sample size was calculated to be 341, using the formula 4pq/T with an allowable error of 10% of P, at 95% CI. Accounting 10% for non response, the final sample size was calculated as 375 (rounded off to 380) [N=380].

Inclusion criteria

Children belonging to the age group of 1 to 60 months irrespective of their morbidity status residing with their families for more than 3 months in Sripuram area whose parents consented for the study were included.

Exclusion criteria

Parents of children who were unwilling to participate in the study were excluded. Children belonging to the age group of 0 to 1 month were also excluded because ARI such as pneumonia is more common among post neonates compared to neonates.

Sampling method

The sampling method used was Simple Random Sampling. The list of under 5 children in this locality which is the sampling frame was obtained from RHTC. From the list consisting of 3494 children residing in the field practice area of RHTC, 380 samples were selected using lottery method.

Study tool

A semi-structured pre-tested questionnaire was used as study tool to interview the child’s mother who was the informant. The questionnaire was prepared in English and translated to the local language Tamil. The interview was conducted by the investigator herself and their responses were recorded in the questionnaire.

Consent and ethical approval

The study was approved by Institutional Ethics Committee of the medical college. After explaining the purpose of study to be conducted in detail to the parents of children below five years, signature was obtained in the consent form from the informant before conducting
the interview and examination. The informed consent form was in Tamil, which is the local language of the study population.

**Data collection method and period**

The data was collected by visiting the designated houses as per the sampling frame. The availability of the mother and child at their residence was confirmed by the field staff. In case the child was admitted in an ICDS or school, a cumulative list was made and they were interviewed only during the weekends. Each participant with informant was interviewed for 5 to 6 minutes.

**Statistical analysis**

Data was analyzed using the software SPSS, version 16. The descriptive statistics analysed were presented as frequency distribution and percentage.

**Operational definition of acute respiratory infection**

A child having at least one of the following recognisable symptoms of ARI such as runny nose, cough, ear discharge, throat pain, noisy breathing and difficult breathing which might be associated with or without fever in the 2 weeks prior to the date of visit.17-19

**RESULTS**

Among the 380 participants, 165 (43.4%) of them belonged to the age group of 1 to 12 months, 145 (38.2%) of them belonged to the age group of 13 to 36 months and 70 (18.4%) of them belonged to the age group of 37 to 60 months. Among the study subjects, 180 (47.4%) were males and 200 were females (52.6%). Majority 322 (84.7%) of them belonged to Hindu religion, 36 (9.5%) were Christians, 22 (5.8%) were Muslims.

Majority, 202 (53.2%) of the participants were from nuclear family and 178 (46.8%) were from joint family. The overall literacy rate of mothers of study participants was 93.9%. Among them 24 (6.3%) of the mothers underwent primary education, 191 (50.3%) of them underwent secondary education, 59 (15.5%) of them underwent higher secondary education and 83 (21.8%) were graduates. 23 (6.1%) mothers are illiterate.

As per modified BG Prasad’s socio economic status classification (2016) 10.8% belonged to upper class, 40.3% belonged to upper middle class, 33.2% belonged to middle class and 15.8% belonged to lower middle class. It was observed that among the study population none of them belonged to lower class (Table 1).

Figure 1 shows the prevalence of acute respiratory infections among under five children. Among the study subjects, 36.6% of them had either cold or runny nose, 27.9% of them had cough, 23.4% of them had stridor, 20.8% of them had reduced intake of food, 2.6% of them had either ear pain or discharge, 2.6% of them had rapid breathing, 1.3% of them had wheeze, 0.8% of them were tired/drowsy, 0.5% of them had throat pain, 0.5% of them had convulsions. It was found that none of the subjects had chest in-drawing and 17.1% of them had symptoms associated with fever (Figure 2).

![Prevalence of ARI](image-url)
In this study, adhering to the operational definition given by National Family Health Survey regarding the symptoms of ARI among under five children, 36.6% of them had either cold or runny nose, 27.9% had cough, 23.4% had stridor, 20.8% had reduced intake of food, 26.5% had either ear pain or discharge, 2.6% had rapid breathing, 1.3% had wheeze, 0.8% was tired/drowsy, 0.5% had throat pain, 0.5% had convulsions and 17.1% of them were associated with fever. In a study carried out by Kumar et al, 52.7% had cold/running nose, 45.4% had cough, 3.3% of had sore throat, 1.2% had ear discharge, 2% had symptoms associated with fever and fast breathing, 47.5% had symptoms associated with fever.16

In a study done by Fekadu et al, 20.6% had cough, 15.7% had fast breathing, 7.7% had fever, 8.4% had wheezing, 21.1% had chest in drawing and 1.7% had stridor.24 In a study carried out by Majumdar et al, 85.7% had cough, 100% had runny nose, 1.8% had ear discharge and none had sore throat.25 Since most of the studies are community based, the results reflect the non-severe forms of pneumonia only such as no pneumonia and pneumonia when compared to severe and very severe pneumonia which is the common cause of morbidity among under five children requiring hospitalisation.

CONCLUSION

This study shows that the prevalence of ARI among children below 5 years of age was 41.6% in the rural field practising area of a medical college in Kancheepuram district which is relatively high. Clear distinction between the prevalence of acute upper and lower respiratory tract infection should be surveyed to know the actual burden of ARI, so that the terms ARI and pneumonia cannot be interchangeably used. Though such community based studies will throw light on the prevalence of non-severe forms of pneumonia and risk factors that predisposes the children to ARI, it is vital to conduct more hospital based studies to know the burden of severe form of pneumonia which contributes to the morbidity and mortality of children below five years of age.
