ABSTRACT

Background: Worldwide the elderly population gradually increasing and that will definitely pose several challenges. Malnutrition is one of the major but neglected problem in elderly. They are at risk of malnutrition due to physical, psychological, social, dietary and environmental risk factors. Malnutrition in elderly is associated with adverse health effects. Hence to study the nutritional status of elderly.

Methods: The study was carried out between January 2016- June 2017. 545 elderly were included in the study. Out of the 6 subcentres, 1 subcentre (Uchagaon) was selected by simple random sampling technique and house to house survey was carried out to select eligible elderly participants in the villages of selected subcentre. Data was collected from eligible elderly by using mini nutritional assessment (MNA) tool.

Results: Majority of the participants (65.1%) were between the age group of 60-69 years. 55% were females. 23.5% were malnourished, 49% were at risk of malnutrition and 27.5% had normal nutritional status.

Conclusions: The present study concluded that majority of the elderly were at risk of malnutrition. There is a need of actions to improve the nutritional status of the elderly.

Keywords: Elderly, Nutritional status, Mini nutritional assessment tool

INTRODUCTION

‘Aging’ is a biological process, not a disease or curse which is inevitable and irreversible. It is associated with many of physiological and biological changes which are progressive. As such there is no standard numerical criterion to define ‘old age’. However United Nations (UN) recommended a cut off of age 60 years and above when referring to elderly population.

Because of increase in ‘life expectancy at birth’ in the last 10 years, the gap in life expectancy at birth drastically reduced between under developed and developing countries. This has lead to gradual increase in elderly population. As per the report of United Nations 2017, world elderly population is expected to rise from 962 million in 2017 to 2.1 billion by 2050 and 3.2 billion in 2100. In India, elderly population was 8.6% as per 2011 census and it is expected to cross 19% by 2050.

Such a rapid rise in elderly population will certainly pose several challenges. The consequences of aging are multiple, complex and most of the time they go unrecognized. As age advances there will be gradual decline in the physical and biological function/s. Psychological and social problems are also faced by the elderly. Malnutrition is one of the major but neglected problem in elderly.

They are at risk of malnutrition due to physical, psychological, social, dietary and environmental risk factors. It is associated with adverse health effects.
The magnitude of malnutrition in elderly is underreported. Nutritional problems are not yet acknowledged by health professionals due to lack of nutritional assessment and intervention as in this age group it is crucial.

To determine the nutritional status of elderly, Nestle’s mini nutritional assessment (MNA) is one of the most recognized screening tool and is used all over the world. Mini nutritional assessment (MNA) is an 18 questionnaire screening tool which consists of 2 sections-screening and assessment with a total scoring of 0 to 30. Based on the scoring of the elderly, nutritional status were classified as normal nutritional status (24-30), at risk of malnutrition (17.5-23.5) and malnourished (<17). It is a non-invasive, in-expensive practical evaluation tool specially designed for elderly to detect malnutrition and those at risk of malnutrition. It has high sensitivity of 96% and specificity of 98%.

In Karnataka, only few studies were conducted to assess the nutritional status of elderly by MNA tool. Hence an attempt was made to carry out the present study on nutritional status assessment of elderly by using MNA tool in rural area of Belagavi district as the majority of elderly live in rural area and very limited information is available on nutritional status of elderly.

METHODS

Study design

The study was a community based cross-sectional study.

Study duration and period

The study was conducted for a period of 1½ years from January 2016 to June 2017.

Source of data

The present study was carried out among the elderly population of Rural Health Training Centre (RHTC), Uchagaon, a rural field practice area of Department of Community Medicine, BIMS, Belagavi.

Sample size

Sample size was estimated by considering the prevalence of malnutrition in elderly as 15% and by using below mentioned formula,

\[ n = \frac{Z^2 pq}{d^2} \]

where, \( n \) = sample size, 
\( Z = \) alpha error= 1.96 
\( p= \) prevalence of malnutrition=15%, 
\( q=100-p=85, \) 
\( d= \) absolute error as 3%

so, \( n = \frac{(1.96)^2 \times 15 \times 85}{3^2} = 544.5 \approx 545 \)

\( n = 545 \)

Hence, the study comprised of total 545 elderly people residing in the study area.

Method of collection of data

A cross sectional study was carried out among the elderly population of RHTC, Uchagaon which caters a total population of 42,461 and has 6 subcentres Out of the 6 subcentres, Uchagaon subcentre was selected by ‘lottery method’ as a simple random sampling technique which covers 2 villages with a total population of 7272.

House to house survey was carried out in the villages of the selected subcentre after applying the selection criteria.

Selection criteria

Persons who were aged ≥60 years, residing in the area for >1 year and who gave consent to participate in the study were included and those who were terminally ill and bedridden were excluded.

Data collection

After obtaining written informed written consent from eligible elderly data was collected using Nestlé’s Mini Nutritional Assessment tool through personal interview. Weight of each elderly’s were recorded by using KRUP’S weighing machine and recorded nearest to 0.1 kg. Height was recorded using portable stadiometer and it was recorded nearest to 0.1 cm. Mid arm and maximum calf circumferences were recorded from each participants using simple measuring tape and readings were recorded nearest to 0.1 cm.

Statistical analysis

The obtained data was entered on a Microsoft Excel Windows 10 spread sheet. The data was analyzed using SPSS version 22.0. The categorical data was expressed in percentages while continuous data was expressed as mean. The association between the MNA score with age and gender were tested using chi-square test. Significance level was considered at ‘p’ value of ≤0.05.

RESULTS

In the present study, total of 545 elderly participants participated in this study out of which, 245 (45%) were males and 300 (55%) were females. Majority of the participants (65.1%) were in the age group of 60-69 years followed by 70-79 years age group (26.6%) and overall the mean age (±SD) of the study participants was 67.84 (±6.38) years (Table 1).

Among the participants aged 60-69 years and 70-79 years, majority were at risk of malnutrition and among the participants aged ≥80 years, majority were malnourished. There was a statistically significant association found between advancing age and low MNA score (Table 3).

Among males, 46.5% were at risk of malnutrition and 21.2% were malnourished. Among females, 51% were at risk of malnutrition and 25.3% were malnourished. However, there was no statistically significant association found between gender and MNA score (Table 4).

**DISCUSSION**

Elderly population is the fastest growing age group than any other age group worldwide including India. As the elderly population increases it certainly poses several challenges on society, particularly on health, economy and social life. Elderly are prone for malnutrition as it is influenced by many factors.

Considering the above facts, a community based cross sectional study was conducted and the study included 545 elderly participants aged 60 years and above residing in Uchagaon, a rural field practice area of Department of Community Medicine, BIMS, Belagavi.

In the present study, almost 2/3rd (65.1%) of the elderly participants were in the age group of 60-69 years with the mean age of 67.84±6.38 years. The finding observed in our study was similar to the study conducted by Kansal et al., Kavya et al and Vedantham et al.10-12 A study conducted by Reddy et al in rural areas of Tamil Nadu observed that the mean age of the entire study population was 68.3 years.

In the present study, nutritional status of elderly using MNA-SF revealed that 19.4% were malnourished, 52.3% were at risk of malnutrition and 28.3% had normal nutritional status. And using complete MNA tool 128 (23.5%) participants were malnourished, 267 (49%) were at risk of malnutrition and 150 (27.5%) had normal nutritional status (Table 2 and Figure 1).
was 69.8±7.8 years which was almost similar to our study.\textsuperscript{15}

A significant association was found between low MNA scoring and advanced age. Study conducted by Paul et al, Agarwal et al and Krithika et al also showed similar association between advanced age and low MNA score.\textsuperscript{9,13,14}

Majority of the participants were between the age group of 65-70 years. Only 8.3% were aged ≥80 years and among them 86.7% were malnourished. This could be because of age related biological and physiological changes that leads to loss of appetite (anorexia of aging) and malnutrition.

In the present study, 55% of the participants were females with female to male ratio of 1.25:1 suggesting female predominance. No significant association was found between gender and MNA score. Studies conducted by Kansal et al and Kavya et al showed similar pattern of distribution with female predominance with no significant association found between gender and MNA scoring.\textsuperscript{10,11}

In contrast, studies conducted by Lahiri et al, Kritika et al and Reddy et al had shown that male participants were more than the females.\textsuperscript{14-16} However there was no significant association between gender and MNA scoring. The female predominance could be because of greater life expectancy in females than males in India.

The present study which was conducted to assess the nutritional status of elderly by using MNA tool revealed, 23.5% were malnourished, 49% were at risk of malnutrition 27.5% had normal nutritional status. The results were almost similar to the study conducted by Kansal et al in other part of rural Belagavi it was observed that, 22.6% of elderly were malnourished and 43.7% were at risk of malnutrition.\textsuperscript{10} This could be because of same geographical and environmental conditions that influenced the elderly nutrition.

A study which was conducted by Kavya et al in rural Bangalore had shown 30.8% of elderly were malnourished and 56% were at risk of malnutrition.\textsuperscript{11} As compared to our study it had shown high prevalence of malnutrition and at risk of malnutrition.

A study by Vedantam et al in rural areas of Tamil Nadu revealed that, 14% of elderly were malnourished and 49% were at risk of malnutrition.\textsuperscript{12} As compared to the present study it showed lower prevalence of malnutrition. Another study by Paul et al in other part of Tamil Nadu had shown 24.4% were at risk of malnutrition and none of the elderly were malnourished.\textsuperscript{13} This could be because of geographical change and health care facilities provided by state government.

Another study conducted by Agarwalla et al in rural Assam revealed that 15% of elderly were malnourished and 55% were at risk of malnutrition.\textsuperscript{9} As compared to our study it had shown lower prevalence of malnutrition but higher ‘at risk’ of malnutrition in elderly.

A study conducted by Ghimire et al in rural areas of Nepal had shown 24% were malnourished and 65% were at risk of malnutrition.\textsuperscript{17} The prevalence of malnutrition and at risk of malnutrition were higher than our study.

The present study was carried out in only one sub centre out of 6 sub centres and thus the results obtained cannot be generalised to entire population of RHTC. Biochemical investigations were not carried out which could help in determining overall nutritional status of elderly.

Conclusion: In the present study, majority of the elderly participants were in the age group of 60-69 years and majority were females. Nutritional assessment of elderly by MNA tool revealed, that majority of the elderly were ‘at risk’ of malnutrition. There was a significant association found between lower MNA score and advanced age.

Regular screening of nutritional status of elderly is required in the rural area. The malnourished elderly need special care regarding the nutritional components and factors which influences their nutritional status. National level elderly nutritional programmes should be implemented.

ACKNOWLEDGEMENTS

We thank to statistician and all the staff members of Department of Community Medicine, BIMS, Belagavi for their suggestions and support. We also thankful to all the elderly of Uchagaon village who participated in this study.

Funding: No funding sources
Conflict of interest: None declared
Ethical approval: The study was approved by the Institutional Ethics Committee from IEC committee, BIMS, Belagavi
