ABSTRACT

Background: An important factor to effectiveness of ART is good adherence to treatment. This study aims to investigate the adherence levels to ART among people living with HIV (PLHIV) attending a Government ART centre in Anakapalli, Andhra Pradesh, India.

Methods: A cross sectional study was done among 1000 adult PLHIV receiving ART. Out of nearly 4500 patients on ART we selected 1000 patients by simple random sampling technique. The average of adherence for a period of 2 years and socio demographic details were taken from the patients treatment card. Chi square test was performed to find out significant difference between the socio-demographic variables and adherence level < 95%.

Results: Out of 1000 patients, 53.9% were male. 42.2% were in age group 31 to 40 years. 50.1 % had adherence >95%. Major factors influencing poor adherence were: decrease in weight (OR=18.65, p=0.000); decrease in CD4 counts (OR=20.12, p=0.000), presence of opportunistic infections (OR=12.67, p=0.000), WHO stage 3 and 4 illness (OR=6.50, p=0.000), travel distance to ART >50 kilometres (OR=1.94, p=0.000), smoker (OR=1.82, p=0.000),being illiterate (OR=1.72, p=0.000), and alcohol consumption (OR=1.58, p=0.001).

Conclusions: Careful monitoring of weight, CD4 counts and opportunistic infections can help to identify poor adherence early.

INTRODUCTION

The estimated number of people living with HIV (PLHIV) globally were 36.7 million at the end of 2015. Nearly 18.2 million PLHIV were on Antiretroviral therapy (ART) by June 2016.¹ The total number of PLHIV in India were 2.1 million at the end of 2015. Of which 44% adults were on ART in India.² Undivided
Andhra Pradesh and Telangana have the highest estimated number of PLHIV (3.95 lakhs) followed by Maharashtra (3.01 lakhs), Karnataka (1.99 lakhs), Gujarat (1.66 lakhs), Bihar (1.51 lakhs) and Uttar Pradesh (1.50 lakhs). As of March 2012 there were 45 ART centres and 89 link ART centres in Andhra Pradesh. Nearly 1,13,106 PLHIV were on first line ART (FLA) in Andhra as of March 2012. The adherence to ART was not much studied in PLHIV on FLA in Andhra. Hence we studied the prevalence of adherence to FLA and risk factors associated with poor adherence in PLHIV on FLA in a Government ART centre in Anakapalli, Visakhapatnam district in Andhra Pradesh.

METHODS

A cross sectional study of 1000 PLHIVs receiving FLA from Government hospital, ART Centre in Area Hospital, Anakapalli, Visakhapatnam district, Andhra Pradesh, India. The period of data collection was between September 2012 to August 2013.

Sample size

Depending upon the feasibility and availability of data we arrived at a sample size of 1000. In Anakapalli ART centre there were 8200 PLHIV registered and nearly 4500 PLHIV were on FLA. From 4500 PLHIV we selected 1000 PLHIV by simple random sampling technique and also based on the inclusion and exclusion criteria.

Inclusion criteria

Inclusion criteria were diagnosed to have HIV infection by ELISA and were on FLA; PLHA on FLA and completed 2 years of ART as of September 2012; age more than 18 years; registered and seeking care from Anakapali ART centre.

Exclusion criteria

Exclusion criteria were PLHIV who have died and stopped treatment.

Data collected

Information pertaining to patients age, sex, occupation, community, educational status, marital status, income and distance of travel from house to ART centre were collected from patients treatment card. Adherence was measured based on the monthly pill counts done by ART counselors while the patients come for monthly collection of drugs. Based on the monthly missed doses the adherence was categorized into 3 different categories.

>95% adherence: The 95% adherence means that the patients have missed less than 3 pills in a month.

80-95% adherence: If the patients have missed 3 to 12 pills in a month we categorized them under 80-95% adherence.

<80% adherence: If the patients have missed more than 12 pills in a month they were categorized to be below <80% adherence.

We computed the monthly adherence for a period of 2 years (2010 and 2011) and then finally took the average adherence for a period of 2 years. The data regarding adherence was also collected from patients ART treatment card. While doing analysis we categorized the levels of adherence into 2 categories as >95% adherence and <95% adherence and did the chi square test.

Ethical clearance

The study was approved by the Ethical committee of the Anakapalli Government district hospital and ART centre.

Statistical analysis

The data collected were entered into excel sheet and analysed using SPSS (Statistical Package for Social Sciences) version 16. The frequency tables for all collected variables were computed. In analysis we grouped the adherence levels into two categories as >95% adherence and <95% adherence. Various socio demographic factors were analyzed to find out the reason for poor adherence (<95%) using chi square test. Multivariate logistic regression analysis was also done.

RESULTS

Nearly 53.9% of the study population were males, 42.2% in the age group 31 to 40 years, 71.1% married, 57.1 were illiterate, 32% smokers and 34.7% were alcohol users. The baseline characteristics were shown in Table 1.

![Figure 1: Percentage of adherence levels on FLA.](image-url)

FLA- First line antiretroviral therapy.
From Figure 1 we can see the different proportion of adherence levels to FLA. Nearly 50.1% showed adherence >95%, 21% between 80-95% and 28.9% had adherence <80%. You can see from Table 2 the different socio demographic variables and personal habits been compared against poor adherence (<95%) in multivariate analysis.

We can see from Table 2 that factors like travel distance to ART >50 kilometers, being illiterate, alcohol consumption, smoking, and diagnosed as WHO clinical staging 3 and 4 were related to poor adherence and it was both statistically significant (p=0.05) and the odds ratio was also greater than 1.

In Table 3 the clinical parameters like weight, opportunistic infections and laboratory investigation parameter like CD4 counts were compared against poor adherence. The odds ratio was very high for clinical and lab parameters. Decrease in CD4 counts (OR=20.12), decrease in weight (OR=18.62) and presence of opportunistic infections (OR=12.67) came as most significant predictors of poor adherence in multivariate analysis.

DISCUSSION

Our study showed nearly 49.9% had poor adherence. A systematic review and meta-analysis study done by Mhaskar et al on adherence to ART in India showed the pooled adherence rate was only 70%.\(^5\) Mhaskar et al study also reflected our study findings of ART adherence levels were below the required levels to have an optimal treatment effect.\(^5\)

We compared the adherence levels to ART with other studies done in India (Table 4).

Two studies done by Rai et al and Hansana et al showed adherence levels <95% as 43% and 40%, which was almost comparable with our studies poor adherence level of 49.9%.\(^5,7\) On the contrary a study done by Anuradha et al found very low levels of poor adherence equivalent to only 3.2%. While other studies found poor adherence levels of 36.3% and 27%.\(^8,10\) The wide differences to poor adherence levels to ART of around 3% to 50% from previous studies may be attributed to difference in sample size, study settings, the methods used to measure adherence levels and also the time duration for adherence measurements.

Table 4: Comparison of adherence levels to ART from previous studies.

Our study showed the most important predictors of poor adherence was decrease in CD4 counts, decrease in weight and presence of opportunistic infections. Even
certain other studies showed a relationship between adherence and CD4 counts. A study done by Ross-Degnan et al showed that the patients with <80% coverage gained significantly less weight than those who were more adherent. A study done by Fonsah et al reported similar findings to our study in terms of opportunistic infections and adherence.

**CONCLUSION**

Even though our study showed factors like travel distance to ART, being illiterate, smoking, and alcohol consumption, had significant relation to poor adherence. The odds of developing poor adherence was very high among clinical parameters like current opportunistic infection, decrease in weight and WHO clinical staging and lab parameter like CD4 counts on multivariate logistic regression analysis.

**Recommendations**

Patients on long term ART with current opportunistic infections, decrease in CD4 counts, decrease in weight and WHO clinical staging 3 and 4 should be suspected for poor adherence and followed up. Counseling related to cessation of smoking and stopping of alcohol consumption to be more emphasized in counseling sessions. The travel distance to ART can be minimized by directing the patients to receive ART from their nearby centres.
